

# Abandoned Coal Mine Methane Opportunities Database

U.S. Environmental Protection Agency  
September 2008

## **Acknowledgement**

This draft was prepared under U.S. Environmental Protection Agency Contract EP-W-05-063 by Raven Ridge Resources, Incorporated.

## Introduction

### Background

Every year, the U.S. EPA publishes and makes available an inventory to identify and quantify the country's anthropogenic sources and sinks of greenhouse gas emissions to fulfill its commitment under the United Nations Framework Convention on Climate Change (UNFCCC). The resulting *U.S. Greenhouse Gas Inventory Report* systematically and consistently estimates national emissions and serves as a critical prerequisite for accounting reductions and evaluating mitigation strategies. According to the inventory, coal mines are a major source of anthropogenic methane emissions in the U.S. Methane emitted from active underground and surface coal mines as well as during post-mining activities accounts for approximately 10% of all U.S. methane emissions.

Beginning in 2004, the *U.S. Greenhouse Gas Inventory Report* has also estimated abandoned mine methane (AMM) emissions. As mines mature and coal seams are mined out, mines are closed and eventually abandoned. Shafts or portals are often filled with gravel and capped with a concrete seal. Vent pipes and boreholes are often plugged in a similar manner to oil and gas wells. When active mining stops, the mine's gas production decreases but does not stop completely. Following an initial decline, abandoned mines can liberate methane at a near-steady rate over an extended period of time. The gas can migrate up through conduits, particularly if they have not been sealed adequately. In addition, diffuse emissions can occur when methane migrates to the surface through cracks and fissures in the strata overlying the coal mine. One factor affecting this process is flooding; some abandoned coal mines may flood as a result of intrusion of groundwater or surface water into the void. Flooded mines typically produce gas for only a few years. According to the inventory, AMM emissions accounted for approximately 5.4 Bcf in 2006, roughly 1% of U.S. anthropogenic methane emissions in that year.

The methodology that has been used since 2004 to estimate AMM emissions resulted from a Coalbed Methane Outreach Program (CMOP) study entitled, "*Methane Emissions from Abandoned Coal Mines in the United States: Emission Inventory Methodology and 1990-2002 Estimates*." CMOP conducted this study to determine the magnitude of AMM emissions in the U.S. and to assess the technical feasibility of including this source in the *U.S. Greenhouse Gas Inventory Report*. The methodology that was developed incorporates quantitative models with coal basin-specific parameters, calibrated with field measurements at several mines. The study furthermore uses the methodology in conjunction with a comprehensive database of U.S. mines abandoned since 1972 to generate an aggregate estimate of AMM emissions for each year from 1990 to 2002. This database of U.S. mines abandoned since 1972 – a list of approximately four hundred (400) mines that were considered "gassy" at the time of closure – is provided in the study appendix. In 2005, in an effort to increase the accuracy of the AMM section of the *U.S. Greenhouse Gas Inventory Report*, a follow-up study was conducted surveying companies that had been involved in mining as well as current surface owners; and anecdotal information was gathered to better categorize the abandoned mines used in the

inventory calculations. For example, a number of mines which were previously classified as unknown with regard to their venting, flooding, or sealing were properly categorized. In addition to developing the 2004 study, CMOP also developed a generalized, universal AMM emissions estimation methodology that has been incorporated as part of the 2006 Emissions Inventory Guidelines for the International Panel on Climate Change (IPCC).

More than just sources of emissions, abandoned mines can also be optimal opportunities for methane utilization projects. In 2008, the International Coal Mine Methane (CMM) Projects Database, developed and maintained by the Methane to Markets Partnership, lists 26 projects that recover and productively use methane from abandoned mines in the U.S. Many other mines exist that can host additional, future projects. To encourage project development in this area, CMOP has focused efforts to make available helpful publications and resources. For example, CMOP developed a report entitled “*U.S. Abandoned Coal Mine Methane Recovery Project Opportunities*,” a selection of case studies of current and potential methane recovery projects at abandoned coal mine sites.

### **Updated Abandoned Coal Mines Database**

In this report, the aforementioned database of 400 mines has been updated to include the results of the 2008 *U.S. Greenhouse Gas Inventory Report* (1990 – 2006) as well as any additional mines that have been abandoned since the 2004 “*Methane Emissions from Abandoned Coal Mines in the United States: Emission Inventory Methodology and 1990-2002 Estimates*” study. The database now includes 443 mines. CMOP hopes that this resource will help interested project developers identify potential project sites.

The updated abandoned mine database includes geographic information about the mines such as state, county, and the coal basin in which it is located. The current status of the mine is provided in the database (sealed, venting, flooded, recovering methane, or unknown if no status is listed) as well as the date the mine was abandoned and the estimated methane emissions in million cubic feet per day (mmcfd) at the time of abandonment. This data is obtained primarily from the US Mine Safety and Health Administration (MSHA) which provides data online at [www.msha.gov](http://www.msha.gov) and in reports provided to EPA. The database of mines has been maintained through the annual completion of the *U.S. Greenhouse Gas Inventory Report*. Mines are added to the database as annual emissions data from MSHA indicate they are no longer active.

Note mines colored blue in the database, such as the “[Darby Fork No 1](#)” mine. These mines have been added to the database since the original database was published in “*Methane Emissions from Abandoned Coal Mines in the United States: Emission Inventory Methodology and 1990-2002 Estimates*.” Additional study has revealed mines for which earlier information was not available, as well as mines abandoned since the time of that report in 2004.

Following the database of mines, a list of state agencies and organizations for relevant states is included. These can be a source of more detailed information on the mines such as ownership information, regulatory considerations, and other conditions within the respective states.
